

Building a magneto-optical trap for rubidium atoms: a practical guide for the intrepid third year

Abstract

Our goal for this project was to develop a procedure by which third-year undergraduate students could build, test, and experiment with a magneto-optical trap (MOT). We successfully constructed a MOT and demonstrated its effectiveness, though our setup required the use of expensive and fiddly fibre optic couples. These were chosen for flexibility; an implementation of the experiment would need only minor modifications to avoid using these.

This document is intended to be both a reflection of our experiences and a guide for a prospective third year laboratory experiment. I will first outline some of the arelevant theory for the experiment, then discuss the experimental procedures required to build the MOT; I will conclude the document with a brief discussion of our results.

Supervised by Andy McCulloch and Robert Scholten

University of Melbourne School of Physics
Thanks also to Alexander Wood for his tireless assistance in the lab.

1 Introduction

Optical trapping methodologies have their origin in the 1970s, when Ashkin (1970) developed what has become known as optical tweezers using electromagnetic gradients.

2 Background theory

2.1 Hyperfine structure of rubidium-85

2.2 Non-allowed and dark transitions

2.3 Saturated absorption spectroscopy

2.4 Doppler cooling

2.5 The Zeeman effect

2.6 Repumping

3 Experimental procedure

3.1 Absorption spectroscopy

3.2 Saturated absorption spectroscopy

3.3 Vacuum cell setup

3.4 Rubidium sources and magnetic coils

4 Results and discussion
